# Chapter 6 The Link Layer and LANs

#### A note on the use of these PowerPoint slides:

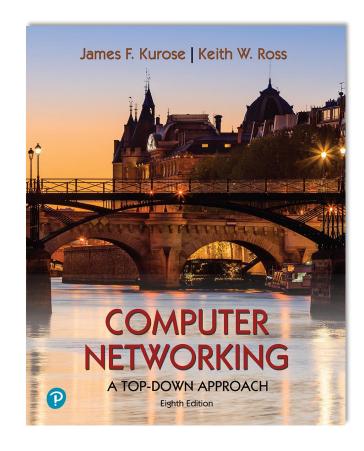

We're making these slides freely available to all (faculty, students, readers). They're in PowerPoint form so you see the animations; and can add, modify, and delete slides (including this one) and slide content to suit your needs. They obviously represent a *lot* of work on our part. In return for use, we only ask the following:

- If you use these slides (e.g., in a class) that you mention their source (after all, we'd like people to use our book!)
- If you post any slides on a www site, that you note that they are adapted from (or perhaps identical to) our slides, and note our copyright of this material.

For a revision history, see the slide note for this page.

Thanks and enjoy! JFK/KWR

# Computer Networking: A Top-Down Approach

8<sup>th</sup> edition Jim Kurose, Keith Ross Pearson, 2020

# Link layer and LANs: our goals

- understand principles behind link layer services:
  - error detection, correction
  - sharing a broadcast channel: multiple access
  - link layer addressing
  - local area networks:
     Ethernet, VLANs
- datacenter networks

 instantiation, implementation of various link layer technologies

# Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANs
- link virtualization: MPLS
- data center networking

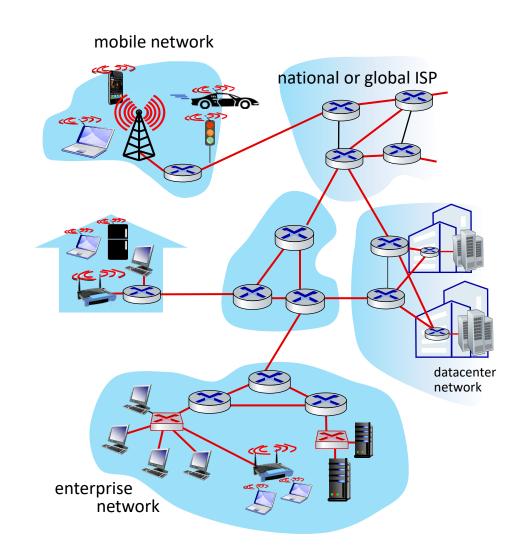

a day in the life of a web request

# Link layer: introduction

#### terminology:

- hosts and routers: nodes
- communication channels that connect adjacent nodes along communication path: links
  - wired
  - wireless
  - LANs
- layer-2 packet: frame, encapsulates datagram

link layer has responsibility of transferring datagram from one node to physically adjacent node over a link

# Link layer: context

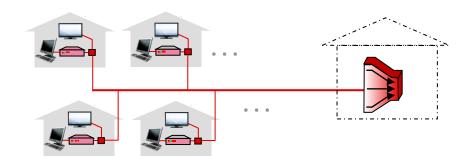

- datagram transferred by different link protocols over different links:
  - e.g., WiFi on first link, Ethernet on next link
- each link protocol provides different services
  - e.g., may or may not provide reliable data transfer over link

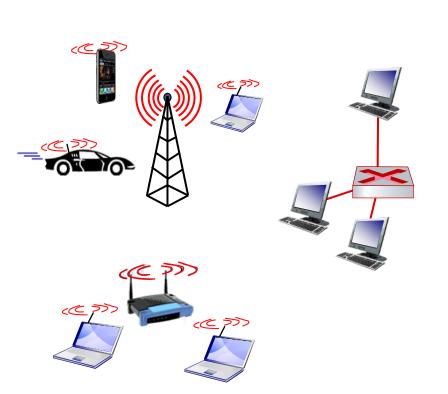

#### transportation analogy:

- trip from Princeton to Lausanne
  - limo: Princeton to JFK
  - plane: JFK to Geneva
  - train: Geneva to Lausanne
- tourist = datagram
- transport segment = communication link
- transportation mode = link-layer protocol
- travel agent = routing algorithm

# Link layer: services

- framing, link access:
  - encapsulate datagram into frame, adding header, trailer
  - channel access if shared medium
  - "MAC" addresses in frame headers identify source, destination (different from IP address!)
- reliable delivery between adjacent nodes
  - we already know how to do this!
  - seldom used on low bit-error links
  - wireless links: high error rates
    - Q: why both link-level and end-end reliability?

# Link layer: services (more)

#### • flow control:

pacing between adjacent sending and receiving nodes

#### error detection:

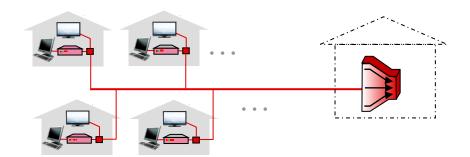

- errors caused by signal attenuation, noise.
- receiver detects errors, signals retransmission, or drops frame

#### error correction:

receiver identifies and corrects bit error(s) without retransmission

#### half-duplex and full-duplex:

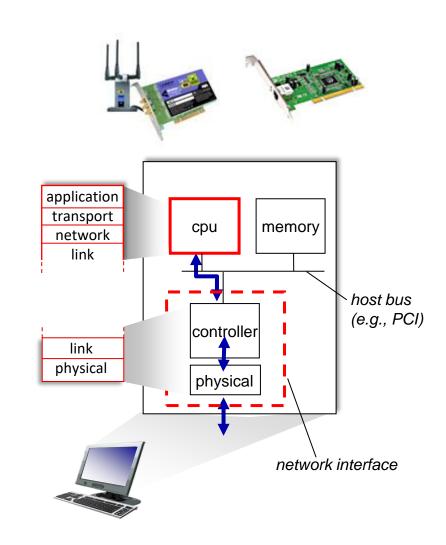

• with half duplex, nodes at both ends of link can transmit, but not at same time

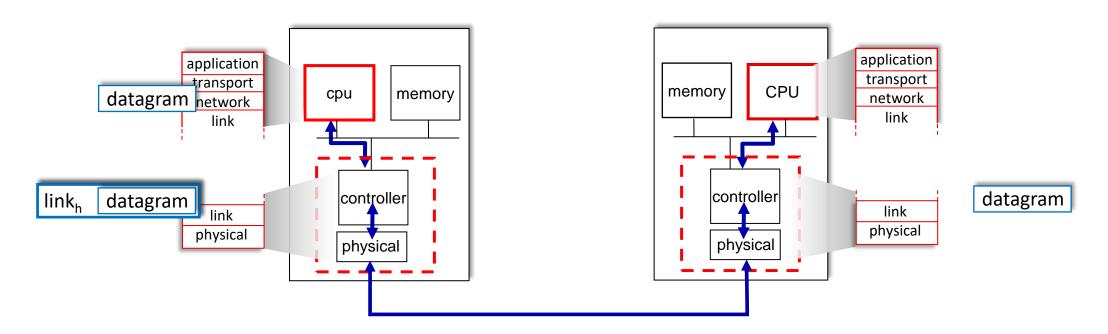

# Where is the link layer implemented?

- in each-and-every host
- link layer implemented in network interface card (NIC) or on a chip
  - Ethernet, WiFi card or chip
  - implements link, physical layer
- attaches into host's system buses
- combination of hardware, software, firmware

## Interfaces communicating

#### sending side:

- encapsulates datagram in frame
- adds error checking bits, reliable data transfer, flow control, etc.

#### receiving side:

- looks for errors, reliable data transfer, flow control, etc.
- extracts datagram, passes to upper layer at receiving side

# Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANs
- link virtualization: MPLS
- data center networking

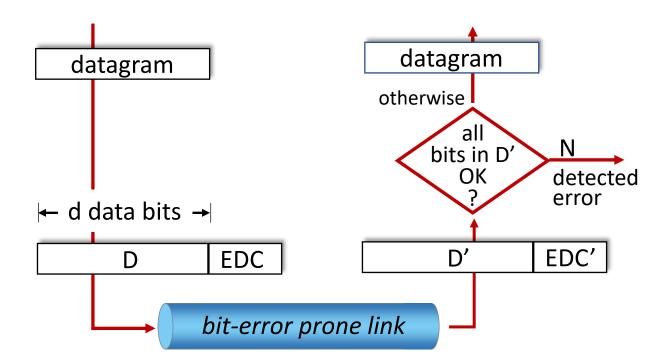

a day in the life of a web request

## **Error detection**

EDC: error detection and correction bits (e.g., redundancy)

D: data protected by error checking, may include header fields

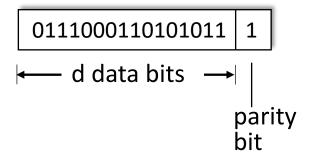

Error detection not 100% reliable!

- protocol may miss some errors, but rarely
- larger EDC field yields better detection and correction

# Parity checking

#### single bit parity:

detect single bit errors

Even parity: set parity bit so there is an even number of 1's

#### two-dimensional bit parity:

detect and correct single bit errors

detected and correctable single-bit error:  $\begin{array}{c|c}
 & 1 & 0 & 1 & 0 & 1 & 1 \\
 & 1 & 0 & 1 & 1 & 0 & 0 \\
\hline
 & 1 & 0 & 1 & 1 & 0 & 0 \\
\hline
 & 0 & 1 & 1 & 0 & 1 & 0 \\
\hline
 & 0 & 1 & 1 & 0 & 1 & 0 \\
\hline
 & 1 & 0 & 1 & 0 & 1 & 0
\end{array}$ 

<sup>\*</sup> Check out the online interactive exercises for more examples: http://gaia.cs.umass.edu/kurose\_ross/interactive/

## Internet checksum (review)

*Goal:* detect errors (*i.e.*, flipped bits) in transmitted segment

#### sender:

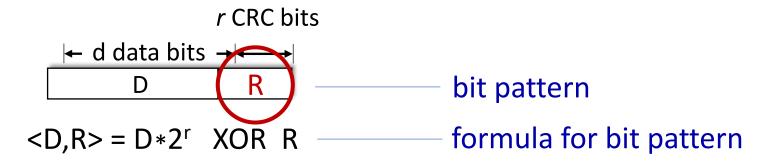

- treat contents of UDP segment (including UDP header fields and IP addresses) as sequence of 16-bit integers
- checksum: addition (one's complement sum) of segment content
- checksum value put into UDP checksum field

#### receiver:

- compute checksum of received segment
- check if computed checksum equals checksum field value:
  - not equal error detected
  - equal no error detected. But maybe errors nonetheless? More later ....

# Cyclic Redundancy Check (CRC)

- more powerful error-detection coding
- D: data bits (given, think of these as a binary number)
- G: bit pattern (generator), of *r+1* bits (given)

*goal*: choose r CRC bits, R, such that <D,R> exactly divisible by G (mod 2)

- receiver knows G, divides <D,R> by G. If non-zero remainder: error detected!
- can detect all burst errors less than r+1 bits
- widely used in practice (Ethernet, 802.11 WiFi)

# Cyclic Redundancy Check (CRC): example

#### We want:

 $D \cdot 2^r XOR R = nG$ 

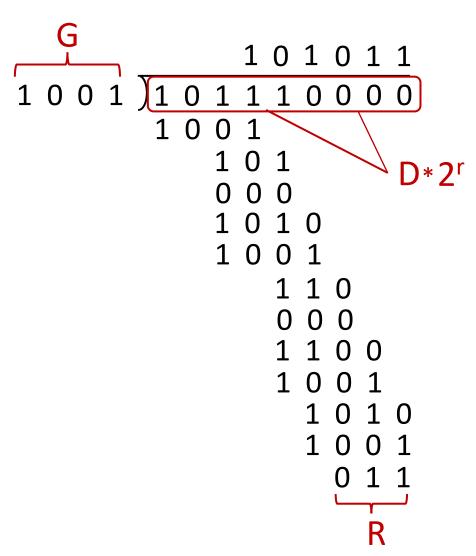

#### or equivalently:

 $D \cdot 2^r = nG XOR R$ 

#### or equivalently:

if we divide D.2<sup>r</sup> by G, want remainder R to satisfy:

$$R = remainder \left[ \frac{D \cdot 2^r}{G} \right]$$

<sup>\*</sup> Check out the online interactive exercises for more examples: http://gaia.cs.umass.edu/kurose\_ross/interactive/

# Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANs
- link virtualization: MPLS
- data center networking

a day in the life of a web request

## Multiple access links, protocols

#### two types of "links":

- point-to-point
  - point-to-point link between Ethernet switch, host
  - PPP for dial-up access
- broadcast (shared wire or medium)
  - old-fashioned Ethernet
  - upstream HFC in cable-based access network
  - 802.11 wireless LAN, 4G/4G. satellite

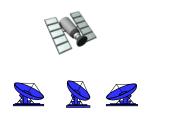

shared wire (e.g., cabled Ethernet)

shared radio: 4G/5G

shared radio: WiFi

shared radio: satellite

humans at a cocktail party (shared air, acoustical)

# Multiple access protocols

- single shared broadcast channel
- two or more simultaneous transmissions by nodes: interference
  - collision if node receives two or more signals at the same time

#### multiple access protocol

- distributed algorithm that determines how nodes share channel,
   i.e., determine when node can transmit
- communication about channel sharing must use channel itself!
  - no out-of-band channel for coordination

## An ideal multiple access protocol

given: multiple access channel (MAC) of rate R bps desiderata:

- 1. when one node wants to transmit, it can send at rate R.
- 2. when M nodes want to transmit, each can send at average rate R/M
- 3. fully decentralized:
  - no special node to coordinate transmissions
  - no synchronization of clocks, slots
- 4. simple

## MAC protocols: taxonomy

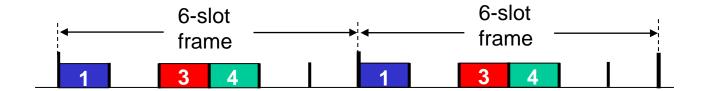

#### three broad classes:

- channel partitioning
  - divide channel into smaller "pieces" (time slots, frequency, code)
  - allocate piece to node for exclusive use
- random access
  - channel not divided, allow collisions
  - "recover" from collisions
- "taking turns"
  - nodes take turns, but nodes with more to send can take longer turns

## Channel partitioning MAC protocols: TDMA

#### TDMA: time division multiple access

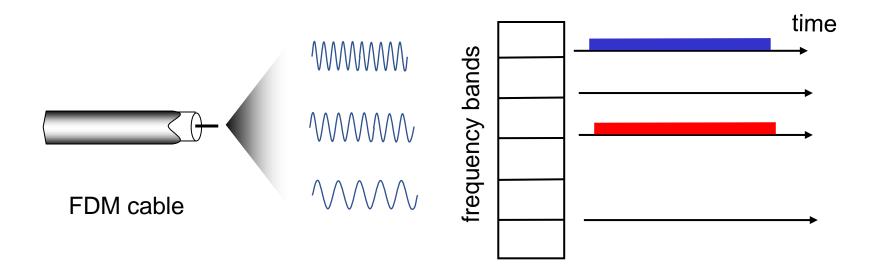

- access to channel in "rounds"
- each station gets fixed length slot (length = packet transmission time) in each round
- unused slots go idle
- example: 6-station LAN, 1,3,4 have packets to send, slots 2,5,6 idle

## Channel partitioning MAC protocols: FDMA

#### FDMA: frequency division multiple access

- channel spectrum divided into frequency bands
- each station assigned fixed frequency band
- unused transmission time in frequency bands go idle
- example: 6-station LAN, 1,3,4 have packet to send, frequency bands 2,5,6 idle

## Random access protocols

- when node has packet to send
  - transmit at full channel data rate R.
  - no a priori coordination among nodes
- two or more transmitting nodes: "collision"
- random access MAC protocol specifies:
  - how to detect collisions
  - how to recover from collisions (e.g., via delayed retransmissions)
- examples of random access MAC protocols:
  - ALOHA, slotted ALOHA
  - CSMA, CSMA/CD, CSMA/CA

## Slotted ALOHA

#### assumptions:

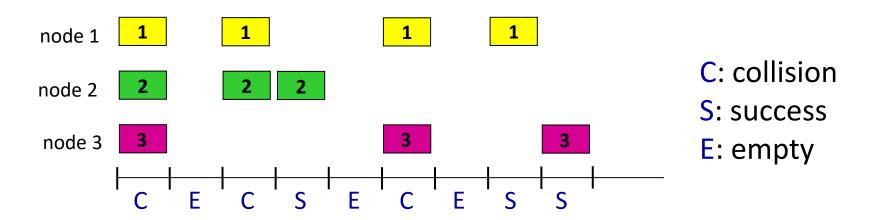

- all frames same size
- time divided into equal size slots (time to transmit 1 frame)
- nodes start to transmit only slot beginning
- nodes are synchronized
- if 2 or more nodes transmit in slot, all nodes detect collision

#### operation:

- when node obtains fresh frame, transmits in next slot
  - if no collision: node can send new frame in next slot
  - *if collision:* node retransmits frame in each subsequent slot with probability *p* until success

randomization – why?

## Slotted ALOHA

#### Pros:

- single active node can continuously transmit at full rate of channel
- highly decentralized: only slots in nodes need to be in sync
- simple

#### Cons:

- collisions, wasting slots
- idle slots
- nodes may be able to detect collision in less than time to transmit packet
- clock synchronization

# Slotted ALOHA: efficiency

efficiency: long-run fraction of successful slots (many nodes, all with many frames to send)

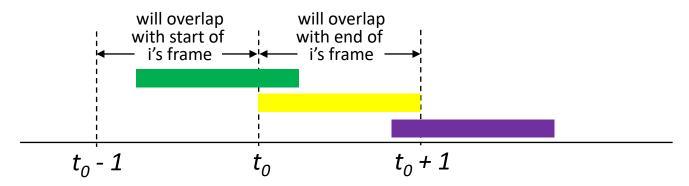

- suppose: N nodes with many frames to send, each transmits in slot with probability p
  - prob that given node has success in a slot =  $p(1-p)^{N-1}$
  - prob that any node has a success =  $Np(1-p)^{N-1}$
  - max efficiency: find  $p^*$  that maximizes  $Np(1-p)^{N-1}$
  - for many nodes, take limit of  $Np^*(1-p^*)^{N-1}$  as N goes to infinity, gives:

```
max\ efficiency = 1/e = .37
```

at best: channel used for useful transmissions 37% of time!

## Pure ALOHA

- unslotted Aloha: simpler, no synchronization
  - when frame first arrives: transmit immediately
- collision probability increases with no synchronization:
  - frame sent at t<sub>0</sub> collides with other frames sent in [t<sub>0</sub>-1,t<sub>0</sub>+1]

pure Aloha efficiency: 18%!

# CSMA (carrier sense multiple access)

#### simple CSMA: listen before transmit:

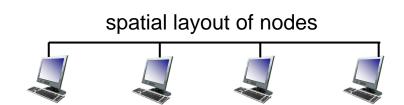

- if channel sensed idle: transmit entire frame
- if channel sensed busy: defer transmission
- human analogy: don't interrupt others!

#### CSMA/CD: CSMA with collision detection

- collisions detected within short time
- colliding transmissions aborted, reducing channel wastage
- collision detection easy in wired, difficult with wireless
- human analogy: the polite conversationalist

## **CSMA**: collisions

- collisions can still occur with carrier sensing:
  - propagation delay means two nodes may not hear each other's juststarted transmission
- collision: entire packet transmission time wasted
  - distance & propagation delay play role in in determining collision probability

 $\mathsf{t}_1^{}$ 

# CSMA/CD:

- CSMA/CS reduces the amount of time wasted in collisions
  - transmission aborted on collision detection

#### spatial layout of nodes

## Ethernet CSMA/CD algorithm

- 1. NIC receives datagram from network layer, creates frame
- 2. If NIC senses channel:

if idle: start frame transmission.

if busy: wait until channel idle, then transmit

- 3. If NIC transmits entire frame without collision, NIC is done with frame!
- 4. If NIC detects another transmission while sending: abort, send jam signal
- 5. After aborting, NIC enters binary (exponential) backoff:
  - after mth collision, NIC chooses K at random from  $\{0,1,2,...,2^m-1\}$ . NIC waits K:512 bit times, returns to Step 2
  - more collisions: longer backoff interval

# CSMA/CD efficiency

- T<sub>prop</sub> = max prop delay between 2 nodes in LAN
- t<sub>trans</sub> = time to transmit max-size frame

$$efficiency = \frac{1}{1 + 5t_{prop}/t_{trans}}$$

- efficiency goes to 1
  - as  $t_{prop}$  goes to 0
  - as  $t_{trans}$  goes to infinity
- better performance than ALOHA: and simple, cheap, decentralized!

# "Taking turns" MAC protocols

#### channel partitioning MAC protocols:

- share channel efficiently and fairly at high load
- inefficient at low load: delay in channel access, 1/N bandwidth allocated even if only 1 active node!

#### random access MAC protocols

- efficient at low load: single node can fully utilize channel
- high load: collision overhead

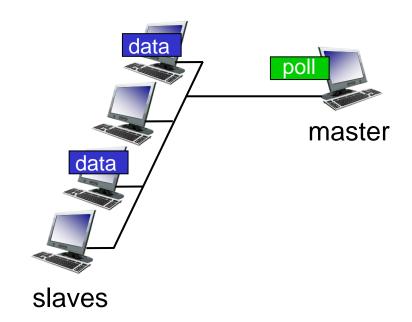

## "taking turns" protocols

look for best of both worlds!

## "Taking turns" MAC protocols

## polling:

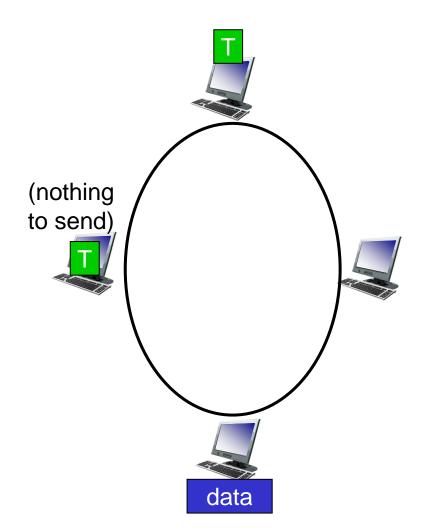

- master node "invites" other nodes to transmit in turn
- typically used with "dumb" devices
- concerns:
  - polling overhead
  - latency
  - single point of failure (master)

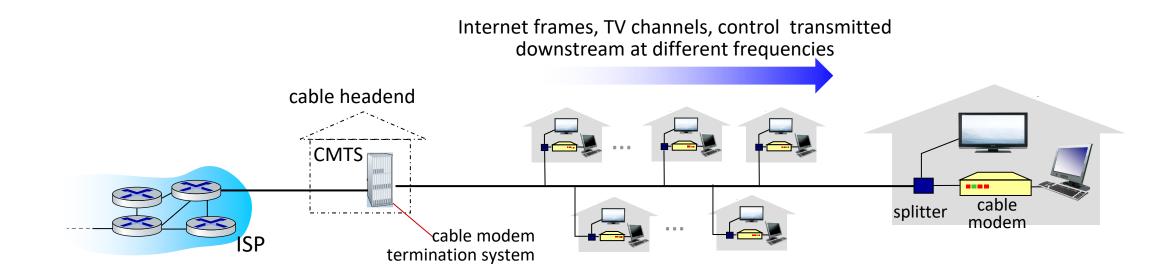

## "Taking turns" MAC protocols

#### token passing:

- control token passed from one node to next sequentially.
- token message
- concerns:
  - token overhead
  - latency
  - single point of failure (token)

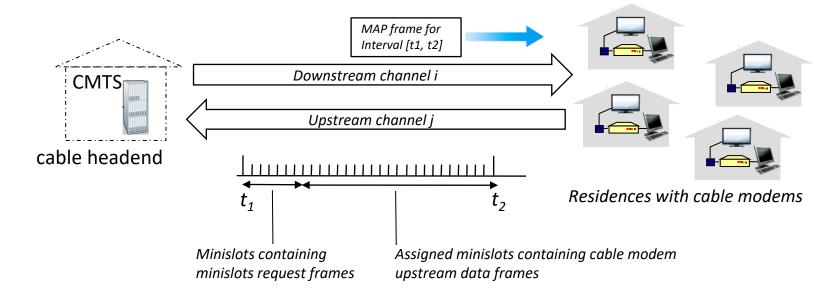

## Cable access network: FDM, TDM and random access!

- multiple downstream (broadcast) FDM channels: up to 1.6 Gbps/channel
  - single CMTS transmits into channels
- multiple upstream channels (up to 1 Gbps/channel)
  - multiple access: all users contend (random access) for certain upstream channel time slots; others assigned TDM

### Cable access network:

### DOCSIS: data over cable service interface specificaiton

- FDM over upstream, downstream frequency channels
- TDM upstream: some slots assigned, some have contention
  - downstream MAP frame: assigns upstream slots
  - request for upstream slots (and data) transmitted random access (binary backoff) in selected slots

### Summary of MAC protocols

- channel partitioning, by time, frequency or code
  - Time Division, Frequency Division
- random access (dynamic),
  - ALOHA, S-ALOHA, CSMA, CSMA/CD
  - carrier sensing: easy in some technologies (wire), hard in others (wireless)
  - CSMA/CD used in Ethernet
  - CSMA/CA used in 802.11
- taking turns
  - polling from central site, token passing
  - Bluetooth, FDDI, token ring

# Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANs
- link virtualization: MPLS
- data center networking

a day in the life of a web request

### MAC addresses

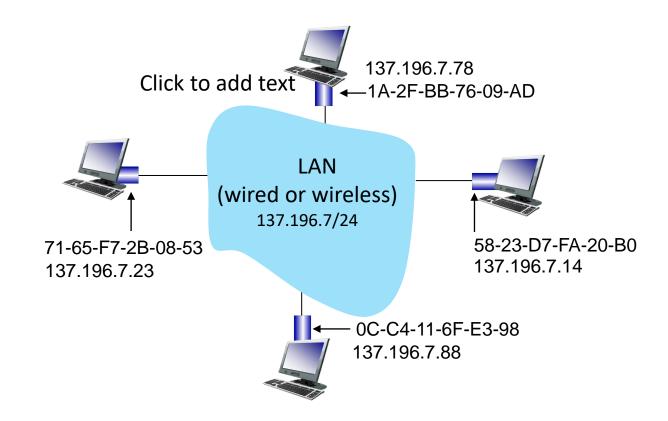

- 32-bit IP address:
  - network-layer address for interface
  - used for layer 3 (network layer) forwarding
  - e.g.: 128.119.40.136
- MAC (or LAN or physical or Ethernet) address:
  - function: used "locally" to get frame from one interface to another physically-connected interface (same subnet, in IP-addressing sense)
  - 48-bit MAC address (for most LANs) burned in NIC ROM, also sometimes software settable
  - e.g.: 1A-2F-BB-76-09-AD

hexadecimal (base 16) notation (each "numeral" represents 4 bits)

### MAC addresses

#### each interface on LAN

- has unique 48-bit MAC address
- has a locally unique 32-bit IP address (as we've seen)

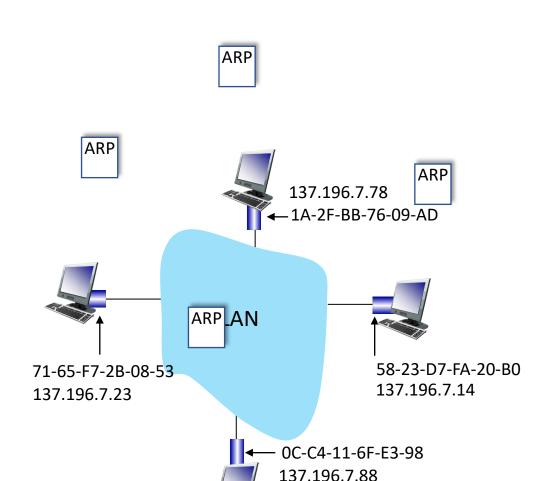

### MAC addresses

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:
  - MAC address: like Social Security Number
  - IP address: like postal address
- MAC flat address: portability
  - can move interface from one LAN to another
  - recall IP address not portable: depends on IP subnet to which node is attached

# ARP: address resolution protocol

Question: how to determine interface's MAC address, knowing its IP address?

ARP table: each IP node (host, router) on LAN has table

 IP/MAC address mappings for some LAN nodes:

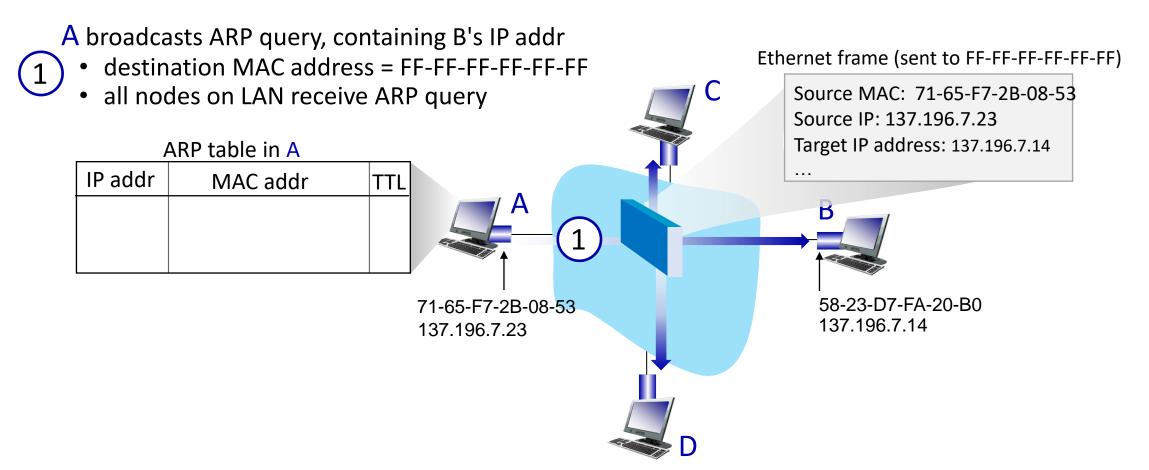

< IP address; MAC address; TTL>

 TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

## ARP protocol in action

### example: A wants to send datagram to B

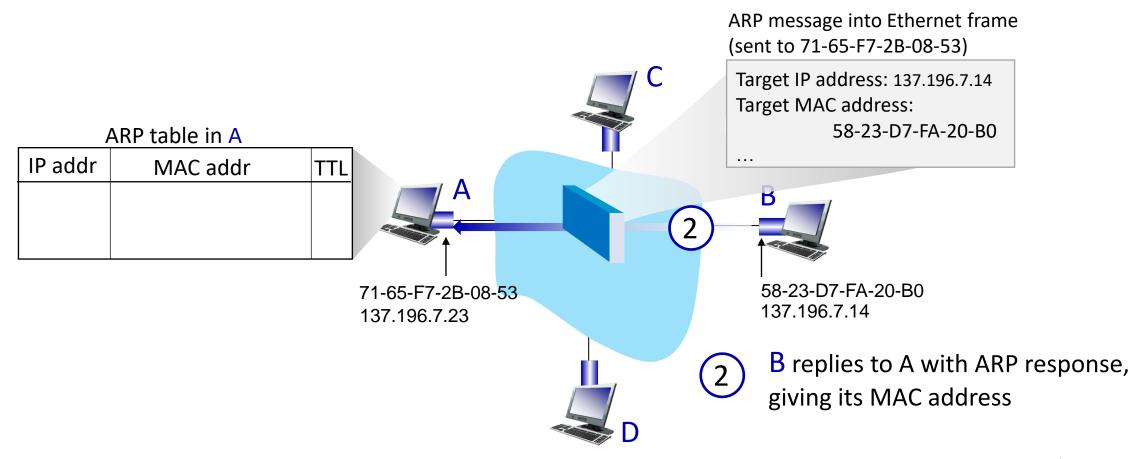

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

### ARP protocol in action

### example: A wants to send datagram to B

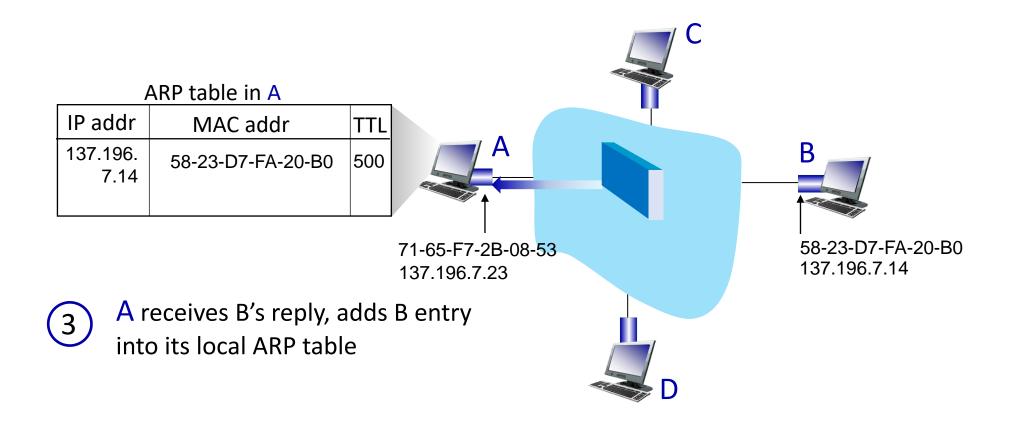

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

# ARP protocol in action

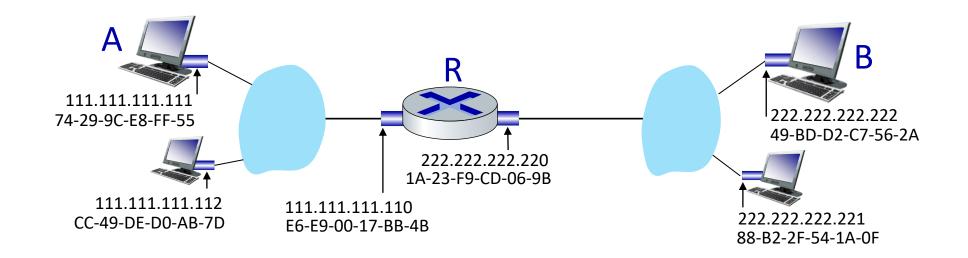

### example: A wants to send datagram to B

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

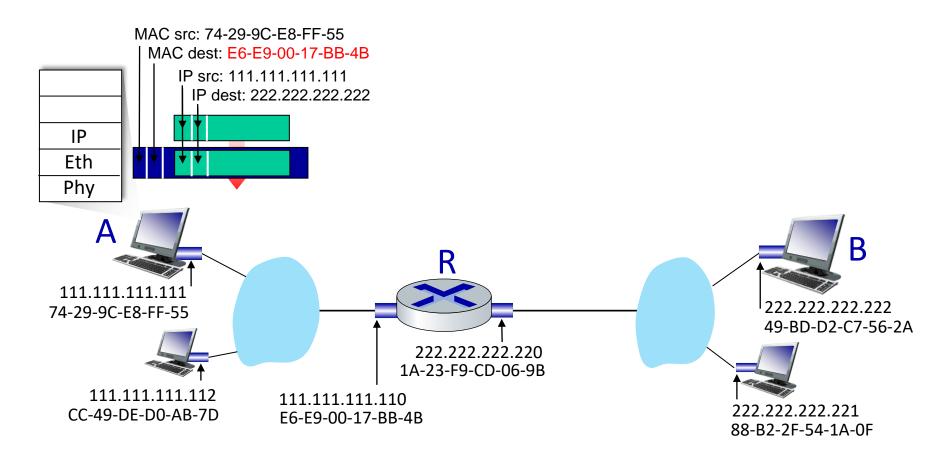

### walkthrough: sending a datagram from A to B via R

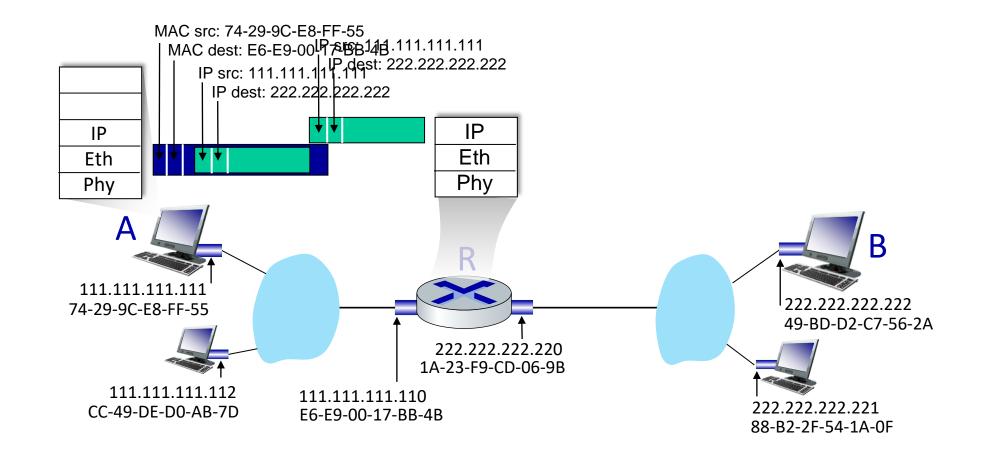

- focus on addressing at IP (datagram) and MAC layer (frame) levels
- assume that:
  - A knows B's IP address
  - A knows IP address of first hop router, R (how?)
  - A knows R's MAC address (how?)

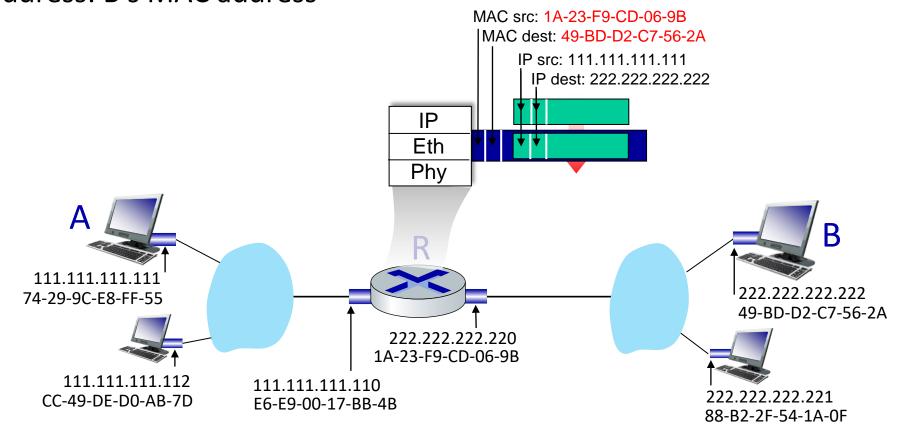

- A creates IP datagram with IP source A, destination B
- A creates link-layer frame containing A-to-B IP datagram
  - R's MAC address is frame's destination

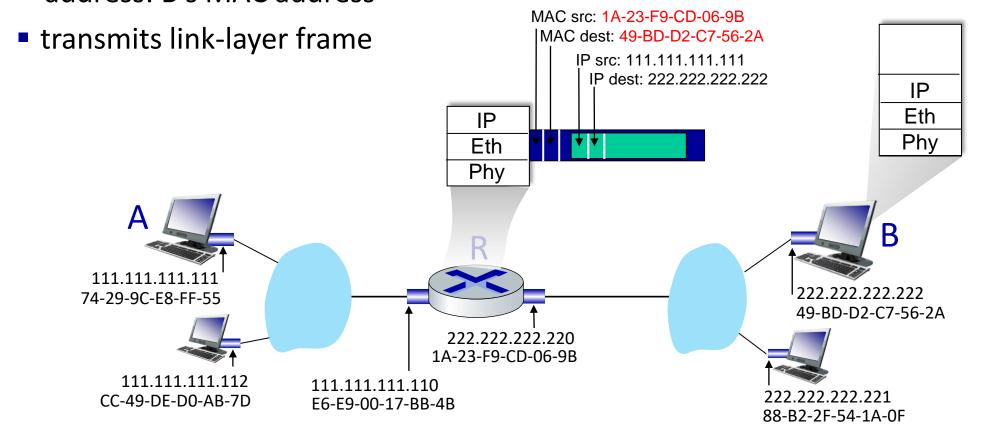

- frame sent from A to R
- frame received at R, datagram removed, passed up to IP

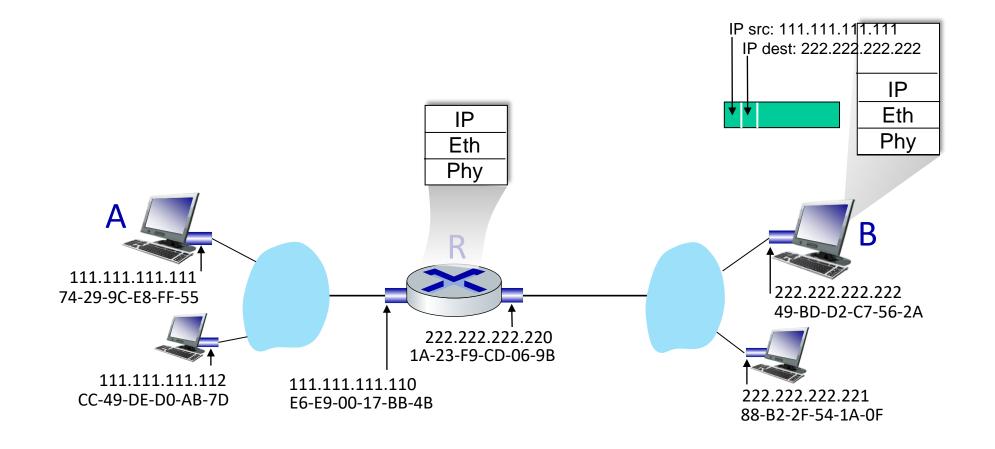

- R determines outgoing interface, passes datagram with IP source A, destination B to link layer
- R creates link-layer frame containing A-to-B IP datagram. Frame destination address: B's MAC address

- R determines outgoing interface, passes datagram with IP source A, destination B to link layer
- R creates link-layer frame containing A-to-B IP datagram. Frame destination address: B's MAC address

- B receives frame, extracts IP datagram destination B
- B passes datagram up protocol stack to IP

# Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANs
- link virtualization: MPLS
- data center networking

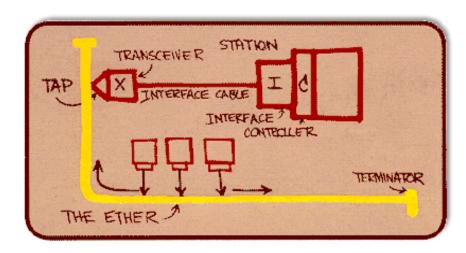

a day in the life of a web request

### Ethernet

### "dominant" wired LAN technology:

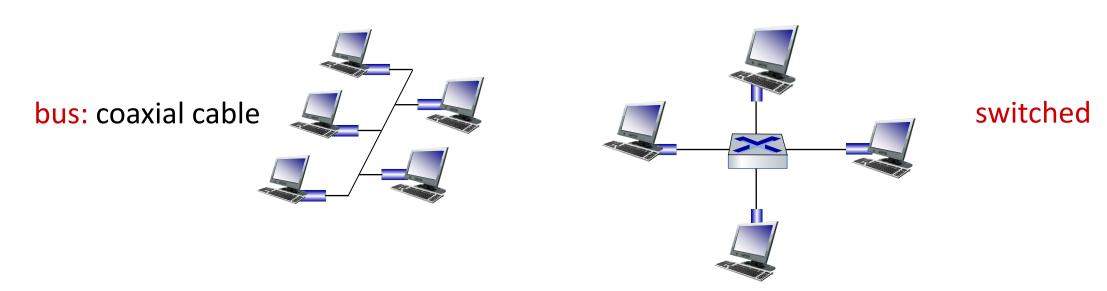

- first widely used LAN technology
- simpler, cheap
- kept up with speed race: 10 Mbps 400 Gbps
- single chip, multiple speeds (e.g., Broadcom BCM5761)

Metcalfe's Ethernet sketch

# Ethernet: physical topology

- bus: popular through mid 90s
  - all nodes in same collision domain (can collide with each other)
- switched: prevails today
  - active link-layer 2 switch in center
  - each "spoke" runs a (separate) Ethernet protocol (nodes do not collide with each other)

### Ethernet frame structure

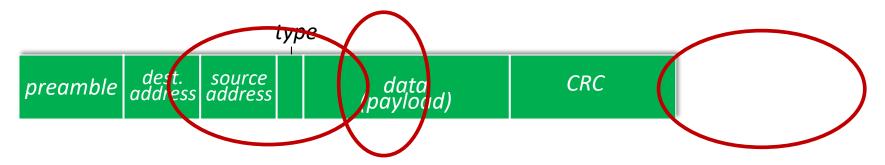

sending interface encapsulates IP datagram (or other network layer protocol packet) in Ethernet frame

#### preamble:

- used to synchronize receiver, sender clock rates
- 7 bytes of 10101010 followed by one byte of 10101011

### Ethernet frame structure (more)

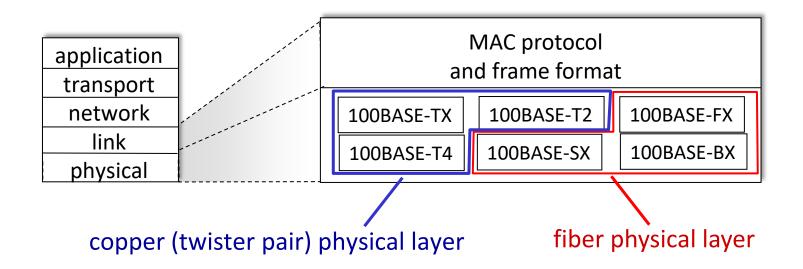

- addresses: 6 byte source, destination MAC addresses
  - if adapter receives frame with matching destination address, or with broadcast address (e.g., ARP packet), it passes data in frame to network layer protocol
  - otherwise, adapter discards frame
- type: indicates higher layer protocol
  - mostly IP but others possible, e.g., Novell IPX, AppleTalk
  - used to demultiplex up at receiver
- CRC: cyclic redundancy check at receiver
  - error detected: frame is dropped

### Ethernet: unreliable, connectionless

- connectionless: no handshaking between sending and receiving NICs
- •unreliable: receiving NIC doesn't send ACKs or NAKs to sending NIC
  - data in dropped frames recovered only if initial sender uses higher layer rdt (e.g., TCP), otherwise dropped data lost
- Ethernet's MAC protocol: unslotted CSMA/CD with binary backoff

### 802.3 Ethernet standards: link & physical layers

- many different Ethernet standards
  - common MAC protocol and frame format
  - different speeds: 2 Mbps, 10 Mbps, 100 Mbps, 1Gbps, 10 Gbps, 40 Gbps
  - different physical layer media: fiber, cable

# Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANs
- link virtualization: MPLS
- data center networking

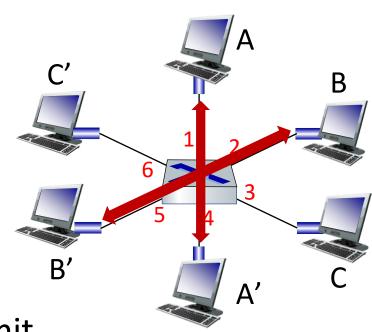

a day in the life of a web request

### Ethernet switch

- Switch is a link-layer device: takes an active role
  - store, forward Ethernet frames
  - examine incoming frame's MAC address, selectively forward frame to one-or-more outgoing links when frame is to be forwarded on segment, uses CSMA/CD to access segment
- transparent: hosts unaware of presence of switches
- plug-and-play, self-learning
  - switches do not need to be configured

# Switch: multiple simultaneous transmissions

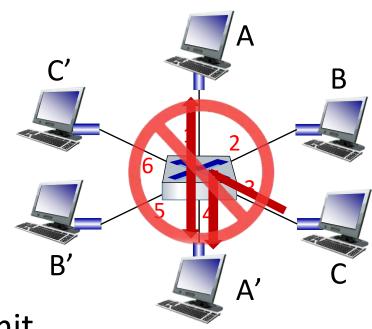

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, so:
  - no collisions; full duplex
  - each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions

switch with six interfaces (1,2,3,4,5,6)

# Switch: multiple simultaneous transmissions

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, so:
  - no collisions; full duplex
  - each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions
  - but A-to-A' and C to A' can not happen simultaneously

switch with six interfaces (1,2,3,4,5,6)

# Switch forwarding table

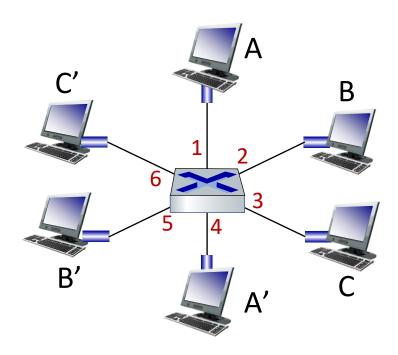

Q: how does switch know A' reachable via interface 4, B' reachable via interface 5?

<u>A:</u> each switch has a switch table, each entry:

- (MAC address of host, interface to reach host, time stamp)
- looks like a routing table!

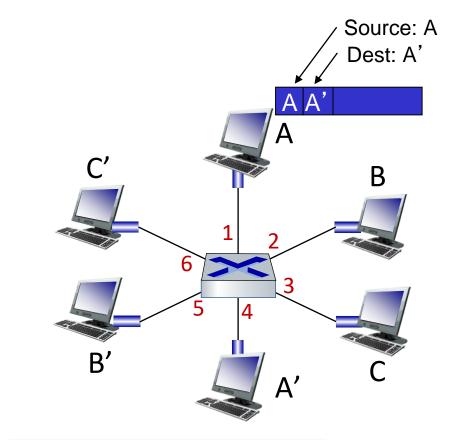

Q: how are entries created, maintained in switch table?

something like a routing protocol?

# Switch: self-learning

- switch *learns* which hosts can be reached through which interfaces
  - when frame received, switch "learns" location of sender: incoming LAN segment
  - records sender/location pair in switch table

MAC addr	interface	TTL
Α	1	60

Switch table (initially empty)

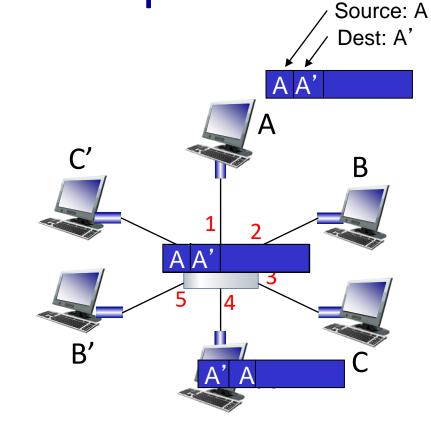

# Switch: frame filtering/forwarding

when frame received at switch:

```
1. record incoming link, MAC address of sending host
2. index switch table using MAC destination address
3. if entry found for destination
  then {
  if destination on segment from which frame arrived
     then drop frame
      else forward frame on interface indicated by entry
   else flood /* forward on all interfaces except arriving interface */
```

Self-learning, forwarding: example

- frame destination, A', location unknown: flood
- destination A location known: selectively send on just one link

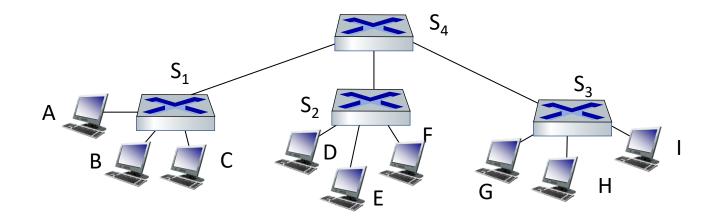

MAC addr	interface	TTL
Α	1	60
Α'	4	60

switch table (initially empty)

## Interconnecting switches

self-learning switches can be connected together:

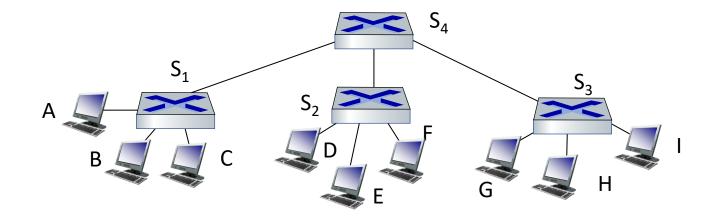

Q: sending from A to G - how does  $S_1$  know to forward frame destined to G via  $S_4$  and  $S_3$ ?

• A: self learning! (works exactly the same as in single-switch case!)

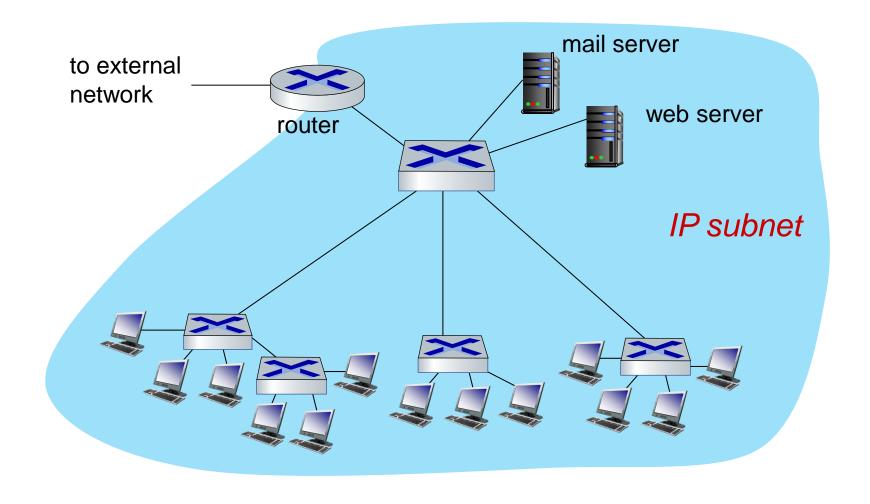

# Self-learning multi-switch example

Suppose C sends frame to I, I responds to C

 $\underline{Q}$ : show switch tables and packet forwarding in  $S_1$ ,  $S_2$ ,  $S_3$ ,  $S_4$ 

### Small institutional network

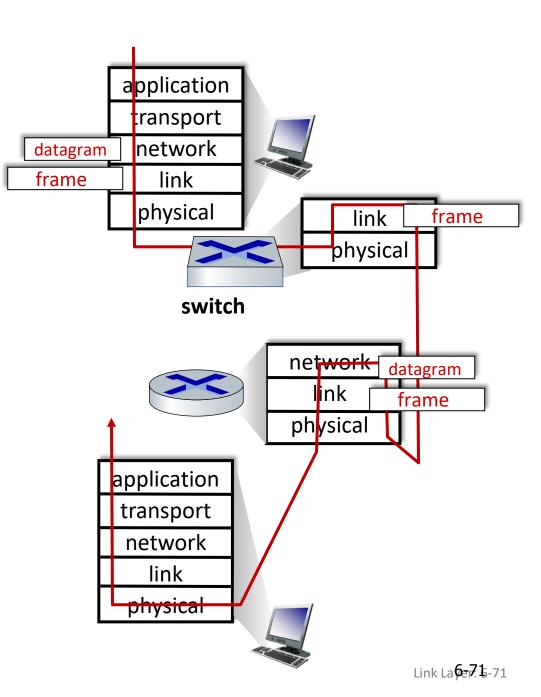

### Switches vs. routers

### both are store-and-forward:

- routers: network-layer devices (examine network-layer headers)
- switches: link-layer devices (examine link-layer headers)

### both have forwarding tables:

- routers: compute tables using routing algorithms, IP addresses
- switches: learn forwarding table using flooding, learning, MAC addresses

# Link layer, LANs: roadmap

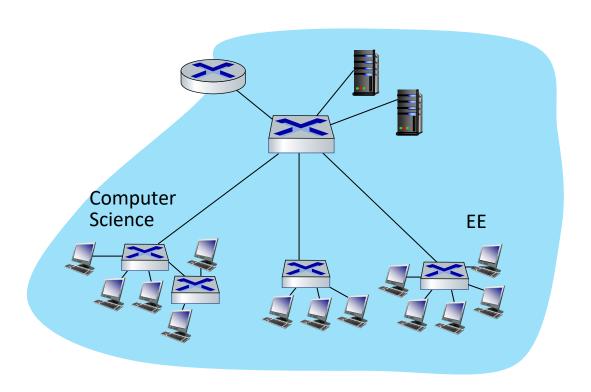

- introduction
- error detection, correction
- multiple access protocols
- LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANs
- link virtualization: MPLS
- data center networking

a day in the life of a web request

## Virtual LANs (VLANs): motivation

Q: what happens as LAN sizes scale, users change point of attachment?

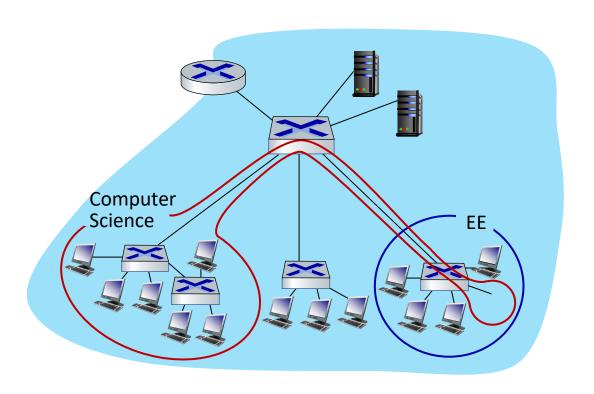

### single broadcast domain:

- scaling: all layer-2 broadcast traffic (ARP, DHCP, unknown MAC) must cross entire LAN
- efficiency, security, privacy issues

## Virtual LANs (VLANs): motivation

Q: what happens as LAN sizes scale, users change point of attachment?

### single broadcast domain:

- scaling: all layer-2 broadcast traffic (ARP, DHCP, unknown MAC) must cross entire LAN
- efficiency, security, privacy, efficiency issues

### administrative issues:

 CS user moves office to EE - physically attached to EE switch, but wants to remain logically attached to CS switch

## Port-based VLANs

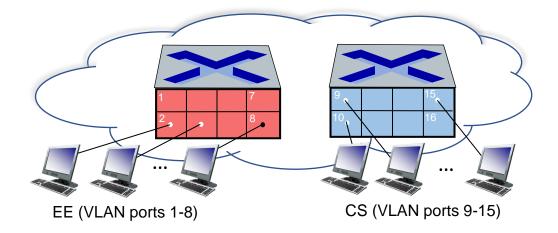

## Virtual Local Area Network (VLAN)

switch(es) supporting VLAN capabilities can be configured to define multiple *virtual* LANS over single physical LAN infrastructure.

port-based VLAN: switch ports grouped (by switch management software) so that single physical switch .....

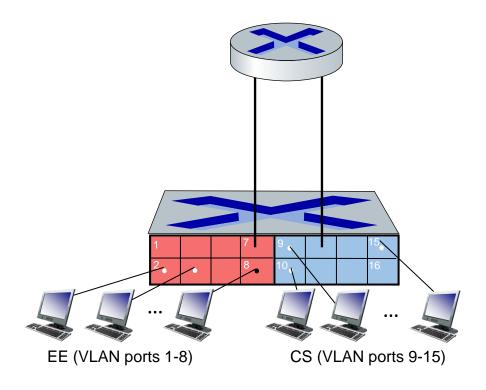

... operates as multiple virtual switches

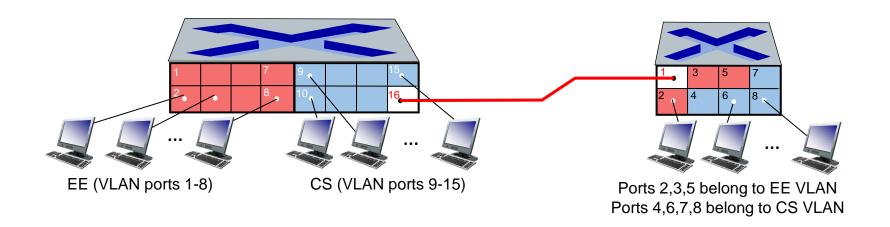

### Port-based VLANs

- traffic isolation: frames to/from ports
   1-8 can only reach ports
  - can also define VLAN based on MAC addresses of endpoints, rather than switch port
- dynamic membership: ports can be dynamically assigned among VLANs
- forwarding between VLANS: done via routing (just as with separate switches)
  - in practice vendors sell combined switches plus routers

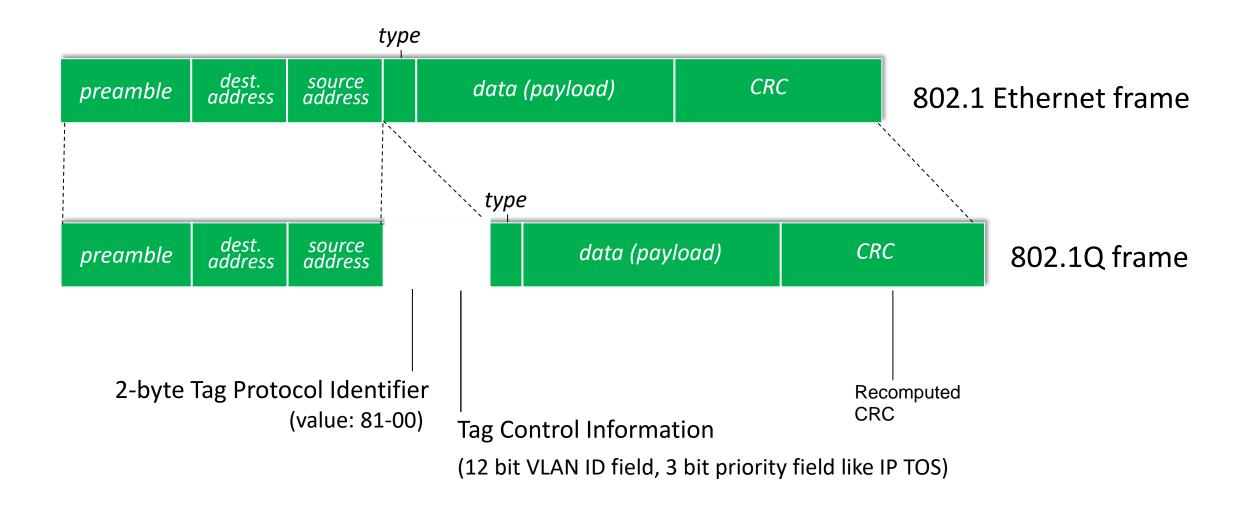

## VLANS spanning multiple switches

trunk port: carries frames between VLANS defined over multiple physical switches

- frames forwarded within VLAN between switches can't be vanilla 802.1 frames (must carry VLAN ID info)
- 802.1q protocol adds/removed additional header fields for frames forwarded between trunk ports

## 802.1Q VLAN frame format

## Link layer, LANs: roadmap

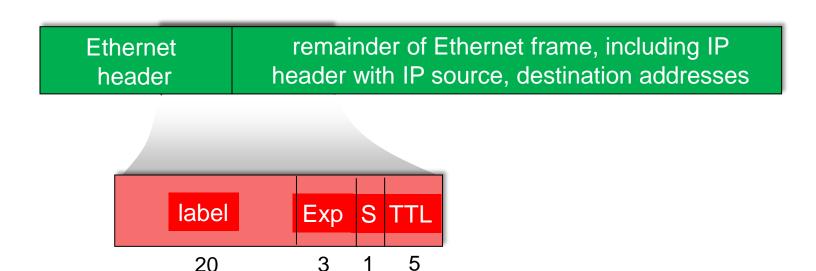

- introduction
- error detection, correction
- multiple access protocols
- LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANs
- link virtualization: MPLS
- data center networking

a day in the life of a web request

## Multiprotocol label switching (MPLS)

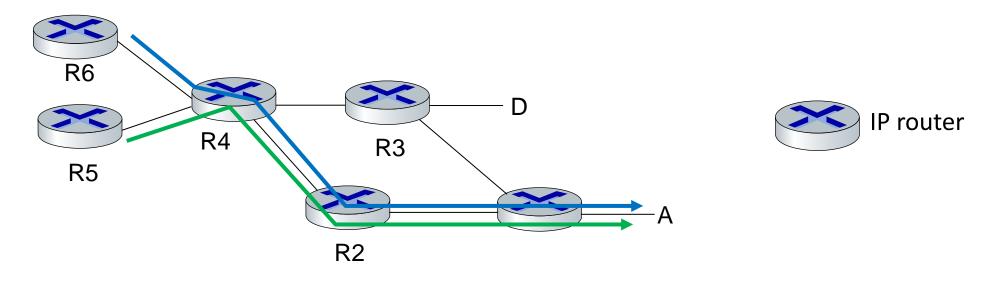

- goal: high-speed IP forwarding among network of MPLS-capable routers, using fixed length label (instead of shortest prefix matching)
  - faster lookup using fixed length identifier
  - borrowing ideas from Virtual Circuit (VC) approach
  - but IP datagram still keeps IP address!

## MPLS capable routers

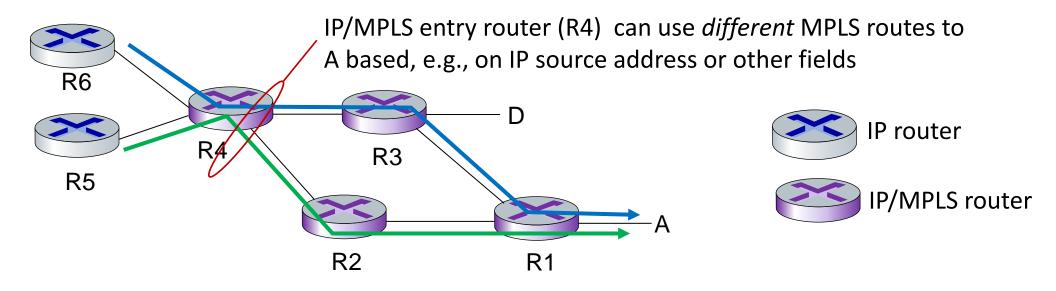

- a.k.a. label-switched router
- forward packets to outgoing interface based only on label value (don't inspect IP address)
  - MPLS forwarding table distinct from IP forwarding tables
- flexibility: MPLS forwarding decisions can differ from those of IP
  - use destination and source addresses to route flows to same destination differently (traffic engineering)
  - re-route flows quickly if link fails: pre-computed backup paths

## MPLS versus IP paths

• IP routing: path to destination determined by destination address alone

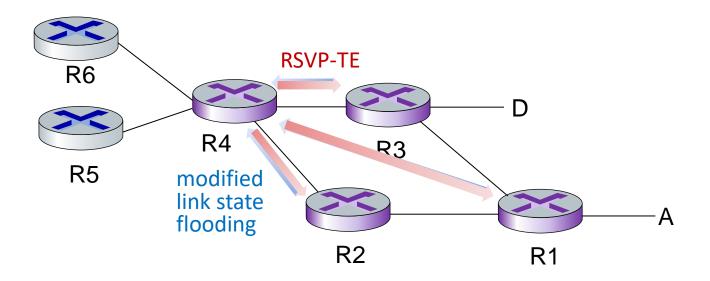

## MPLS versus IP paths

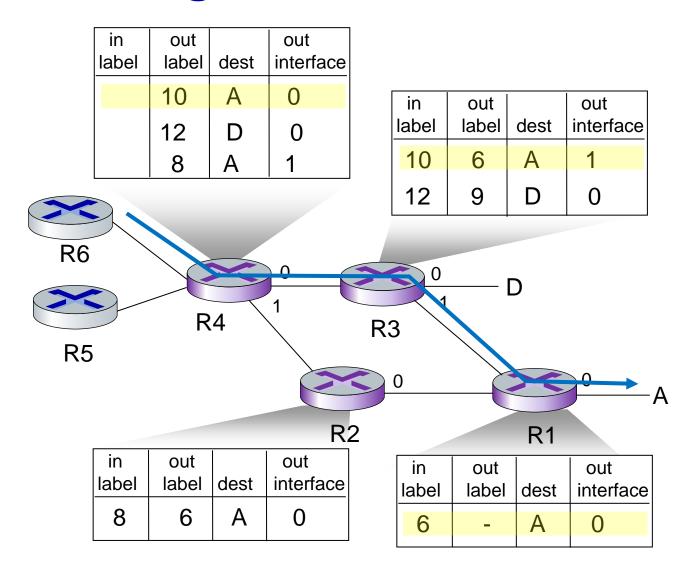

- IP routing: path to destination determined by destination address alone
- MPLS routing: path to destination can be based on source and destination address
  - flavor of generalized forwarding (MPLS 10 years earlier)
  - fast reroute: precompute backup routes in case of link failure

## MPLS signaling

- modify OSPF, IS-IS link-state flooding protocols to carry infoused by MPLS routing:
  - e.g., link bandwidth, amount of "reserved" link bandwidth
- entry MPLS router uses RSVP-TE signaling protocol to set up MPLS forwarding at downstream routers

## MPLS forwarding tables

## Link layer, LANs: roadmap

- introduction
- error detection, correction
- multiple access protocols
- LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANs
- link virtualization: MPLS
- data center networking

a day in the life of a web request

## Datacenter networks

## 10's to 100's of thousands of hosts, often closely coupled, in close proximity:

- e-business (e.g. Amazon)
- content-servers (e.g., YouTube, Akamai, Apple, Microsoft)
- search engines, data mining (e.g., Google)

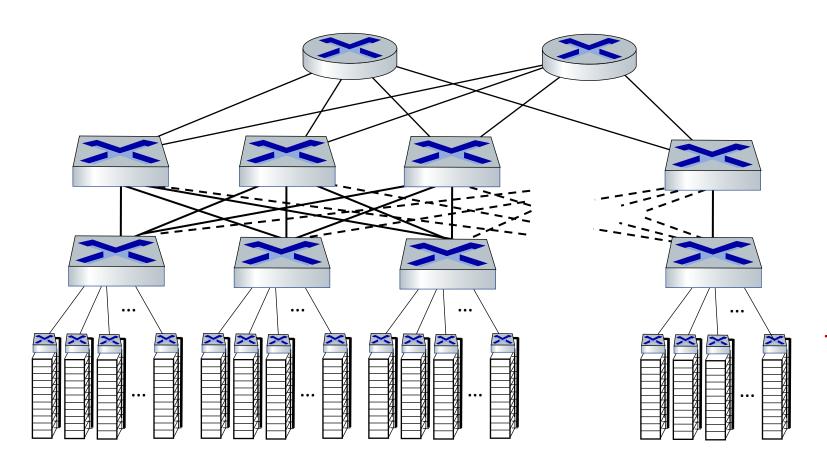

### challenges:

- multiple applications, each serving massive numbers of clients
- reliability
- managing/balancing load, avoiding processing, networking, data bottlenecks

Inside a 40-ft Microsoft container, Chicago data center

## Datacenter networks: network elements

#### **Border routers**

connections outside datacenter

#### Tier-1 switches

connecting to ~16 T-2s below

### Tier-2 switches

connecting to ~16 TORs below

### Top of Rack (TOR) switch

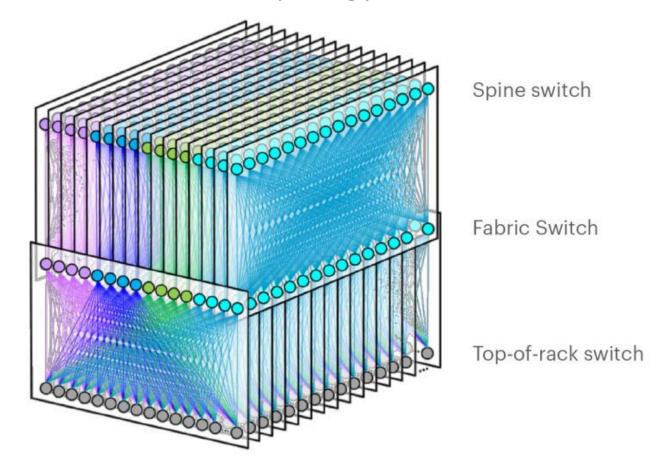

- one per rack
- 40-100Gbps Ethernet to blades

### Server racks

20- 40 server blades: hosts

## Datacenter networks: network elements

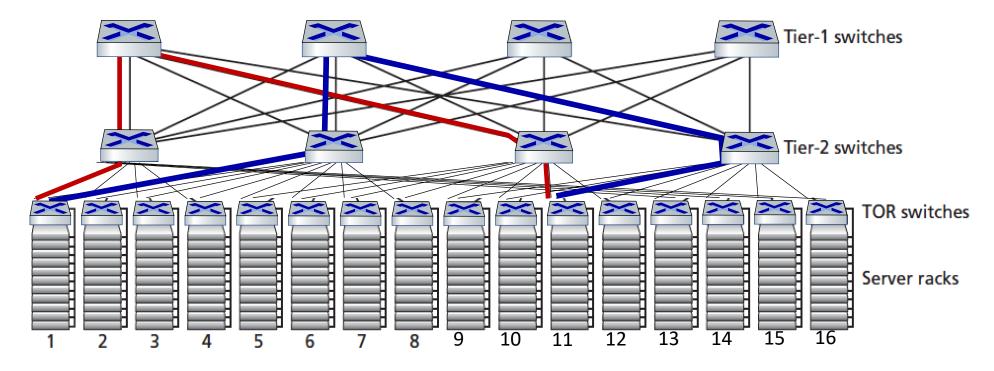

Facebook F16 data center network topology:

https://engineering.fb.com/data-center-engineering/f16-minipack/ (posted 3/2019)

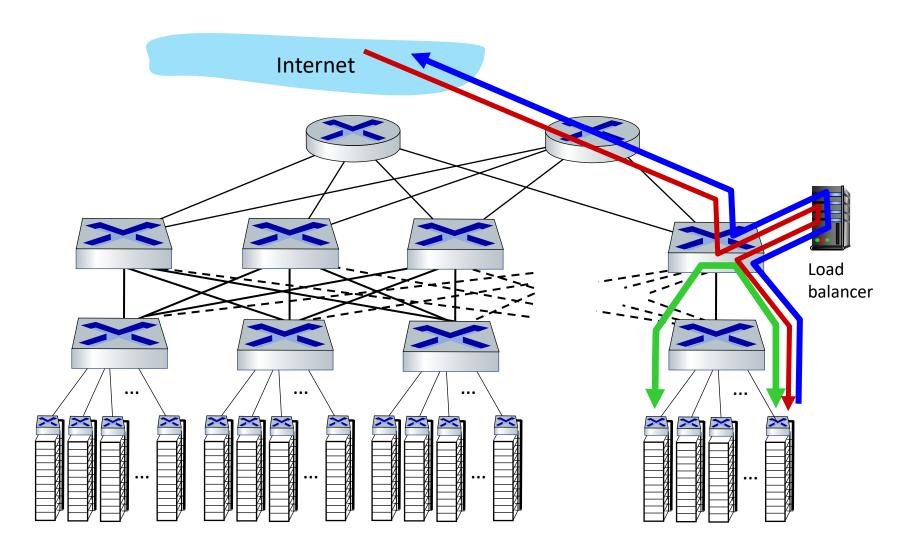

## Datacenter networks: multipath

- rich interconnection among switches, racks:
  - increased throughput between racks (multiple routing paths possible)
  - increased reliability via redundancy

two disjoint paths highlighted between racks 1 and 11

## Datacenter networks: application-layer routing

# load balancer: application-layer routing

- receives external client requests
- directs workload within data center
- returns results to external client (hiding data center internals from client)

## Datacenter networks: protocol innovations

### link layer:

• RoCE: remote DMA (RDMA) over Converged Ethernet

### transport layer:

- ECN (explicit congestion notification) used in transport-layer congestion control (DCTCP, DCQCN)
- experimentation with hop-by-hop (backpressure) congestion control

### routing, management:

- SDN widely used within/among organizations' datacenters
- place related services, data as close as possible (e.g., in same rack or nearby rack) to minimize tier-2, tier-1 communication
